

Networks and Community Detection

Joshua Mankelow

January 27, 2022

Abstract

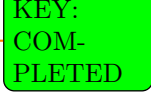

Networks are a great model for analysing and understanding real world complex systems. A very important feature of these network models is *community detection*. Community detection allows us to identify clusters in the network that are well connected amongst eachother. If a network is being used to model a real world system then finding this structure has many implications about the behaviour of the system. This essay will discuss multiple methods for community detection in networks and their applications to the analysis and understanding of real world complex systems.

1 Introduction to Networks

Networks in the technical sense are analogous to networks in the nontechnical sense - a collection of objects paired with a number of connections that can link any two objects. *Networks: An Introduction* by Mark Newman lists *Technological Networks*, *Social Networks*, *Information Networks* and *Biological Networks* as different systems that are modelled by the technical interpretation of a network.[New10, Contents]. A brief example of a network would be something like the following: Imagine you and your friends are represented as dots (nodes or vertices) on a piece of paper. Then if any two people are friends, the dots representing those people are connected by a line (edge). If you then repeat this process by asking your friends to list all their friends and so on, you will end up with a simple model of a *social network*.

SEC: Introduce Network Theory

As one might imagine, now that we have this model it's easy to be curious about any structure that emerges that we can detect and abuse to develop an understanding of the real world system that we are representing. The structure that this essay will explore is that of *communities*. Vaguely speaking, communities are subsets of a network that are *densely connected* amongst themselves. I.e. there is some notion of any node within a community being more closely connected to other nodes in the community than nodes outside the community in the average case. Before we dive into the details of communities and detecting them, I wish to provide some motivation by way of example of the kinds of situations that networks can arise and why they are the natural model for the related systems.

1.1 Social Networks

To better illustrate the simple notion of a social network mentioned above, I will introduce the canonical network theory example of *Zachary's Karate Club*. Zachary's Karate Club is a dataset where "The data was collected from the members of a university karate club by Wayne Zachary in 1977. Each node represents a member of the club, and each edge represents a tie between two members of the club." [kon17, Metadata]. In Figure 1, there are two different renderings of the Zachary Karate Club. Figure 1a shows the network rendered using a "spring" layout (which is a type of force directed graph drawing[Kob12]) and figure 1b shows the network rendered using a "circle" layout. These different layouts show us different parts of the underlying structure of the network.
